[Fire *] Climate

- It's the measures of extreme weather in the first summer after fire that we're interested in.
- And because plots burn at different times, these measures of extreme weather vary among plots.

[Fire *] Climate

Consecutive Dry Days [<1 mm]
Consecutive Hot Days [$>95\%$]
Consecutive Drought Days [$SPEI < -1$]

in the first summer after fire...
[that vary among plots!]

Botanical Research Unit, Stellenbosch and Bolus Herbarium, University of Cape Town

Invasive alien woody plants in the Cape of Good Hope Nature Reserve. II. Results of a second survey from 1976 to 1980

H.C. Taylor, Susan A. Macdonald and I.A.W. Macdonald

Botanical Research Unit, Stellenbosch, Bolus Herbarium, University of Cape Town and Percy FitzPatrick Institute, University of Cape Town

- Surveys of 200m radius around plots in 1966 and 1976-80
- Intensive clearing occurred in the early 80's, with good follow-up
- Used highest density recorded across both surveys

Results: Change in Species Number

Results: Change in Species Number

Results: Change in Species Number

Conclusions

- Clear legacy impact of historical (pre-1990) woody alien species invasion (esp *Acacia cyclops*).
 - Seeder species and shrubs most severely impacted

Conclusions

- Clear legacy impact of historical (pre-1990) woody alien species invasion (esp *Acacia cyclops*).
 - Seeder species and shrubs most severely impacted
- Clear impact of longer periods of hot and dry days in the first summer after fire (and these are becoming more severe).
 - Sprouter species, graminoids and herbs most effected
 - This interaction between fire and climate change is of great concern in crown-fire ecosystems like more Mediterranean-Type Ecosystems

 - Sprouter species, graminoids and herbs most effected
 - This interaction between fire and climate change is of great concern in crown-fire ecosystems like more Mediterranean-Type Ecosystems
- One has to consider multiple drivers of change when exploring patterns in long-term observation datasets.

Conclusions

- Clear legacy impact of historical (pre-1990) woody alien species invasion (esp *Acacia cyclops*).
 - Seeder species and shrubs most severely impacted
- Clear impact of longer periods of hot and dry days in the first summer after fire (and these are becoming more severe).
 - Sprouter species, graminoids and herbs most effected
 - This interaction between fire and climate change is of great concern in crown-fire ecosystems like more Mediterranean-Type Ecosystems
- One has to consider multiple drivers of change when exploring patterns in long-term observation datasets.
- One has to account for differences in post-fire vegetation age (or numbers of individuals) when comparing diversity in Fynbos sites through time.

Implications for management and research

- For rare species, we could consider retaining patches/
populations of mature individuals in case of recruitment
failure/summer mortality
 - BUT!!! Pathogens may be a problem...
- Bet hedging strategies like being able to skip a fire interval
(~seed dormancy) may be a key trait conveying resilience in
the short term?
 - Anecdotal evidence, but needs further attention...
- We need to know what's happening to species other than the
Proteaceae...
